

Figure 5

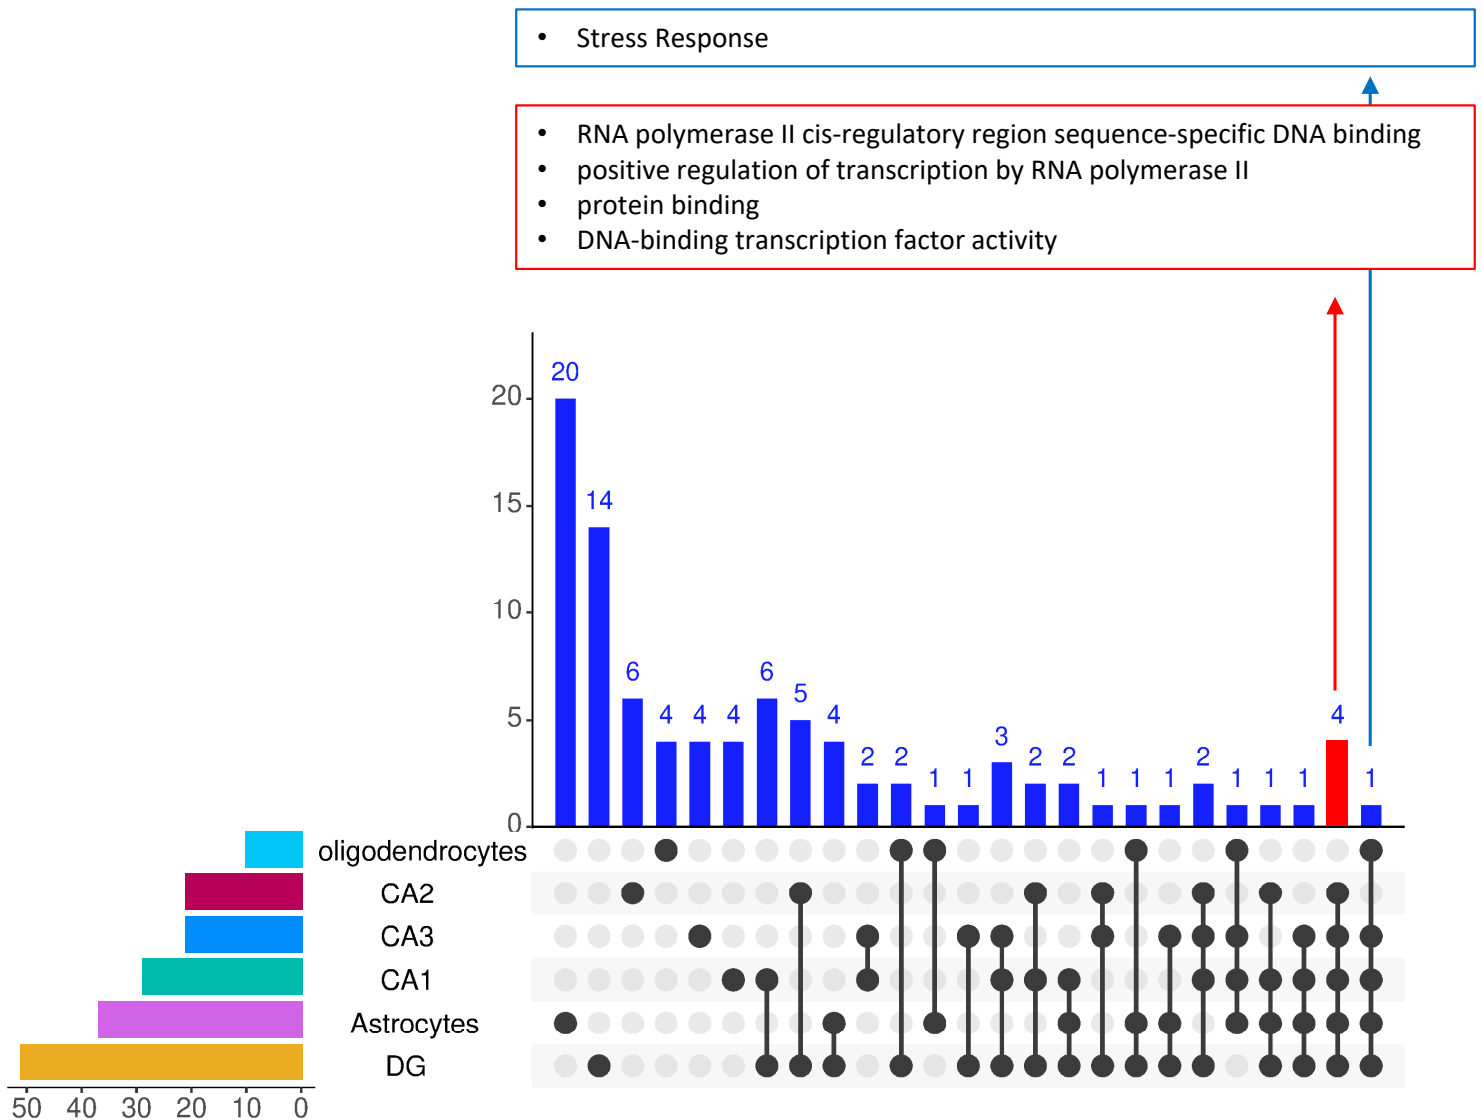

Figure 5: Diverse responses to acute sleep deprivation among the cell types.

The significant DEGs from each cell type were used to predict biological pathways that are enriched in response to an acute sleep deprivation. The numbers above the horizontal bars represent the numbers of biological pathways identified for the cell types that are marked with the closed circles in the bottom panel. There was no pathway that was enriched in all cell types shown. Three pathways were seen in the four cell types to be enriched, while the majority of the pathways were unique to a cell type.

Figure 6

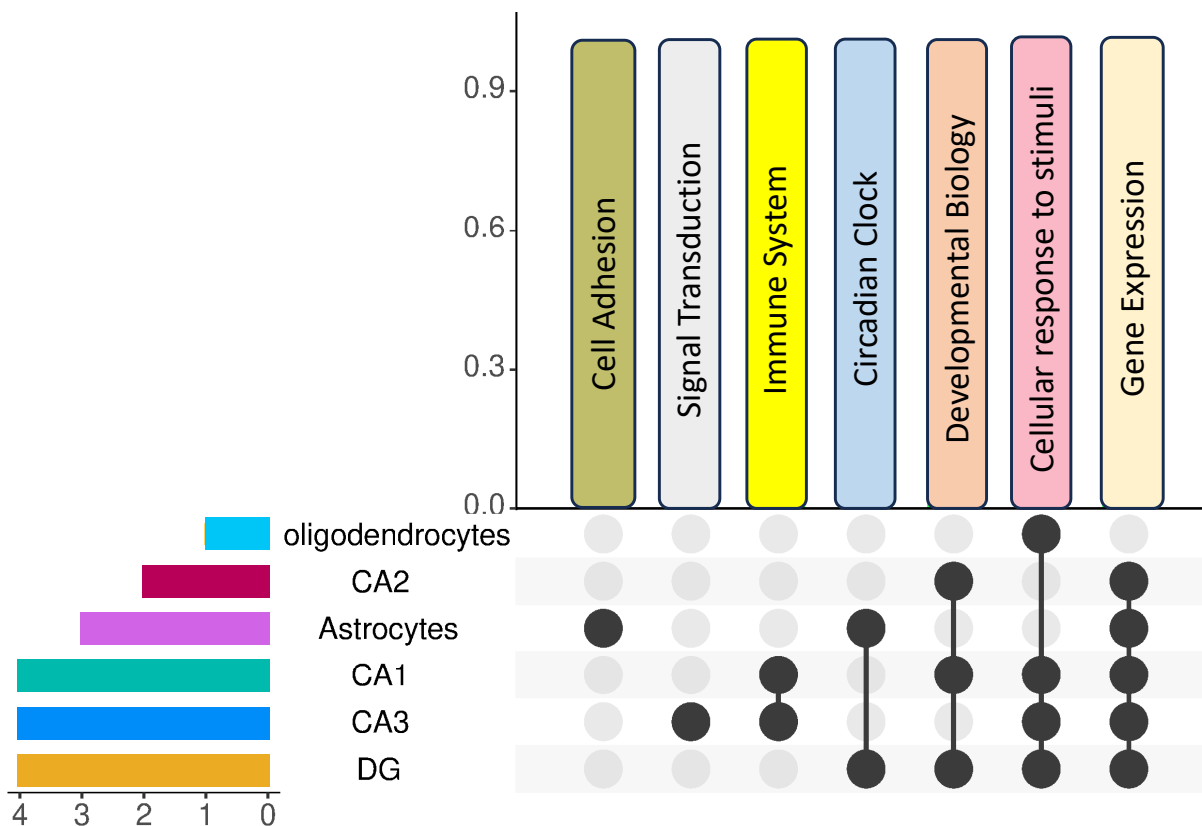

Figure 6: Diverse responses to acute sleep deprivation among the cell types.

A cell type specific enriched pathways were further clustered by their primary function into broader biological categories. An Upset plot shows the overlap of these clusters. Alternations in “the Gene Expression” were seen in five cell types out of six, while two clusters are unique to specific cell types, no single cluster is shared among all of them.

Figure 7

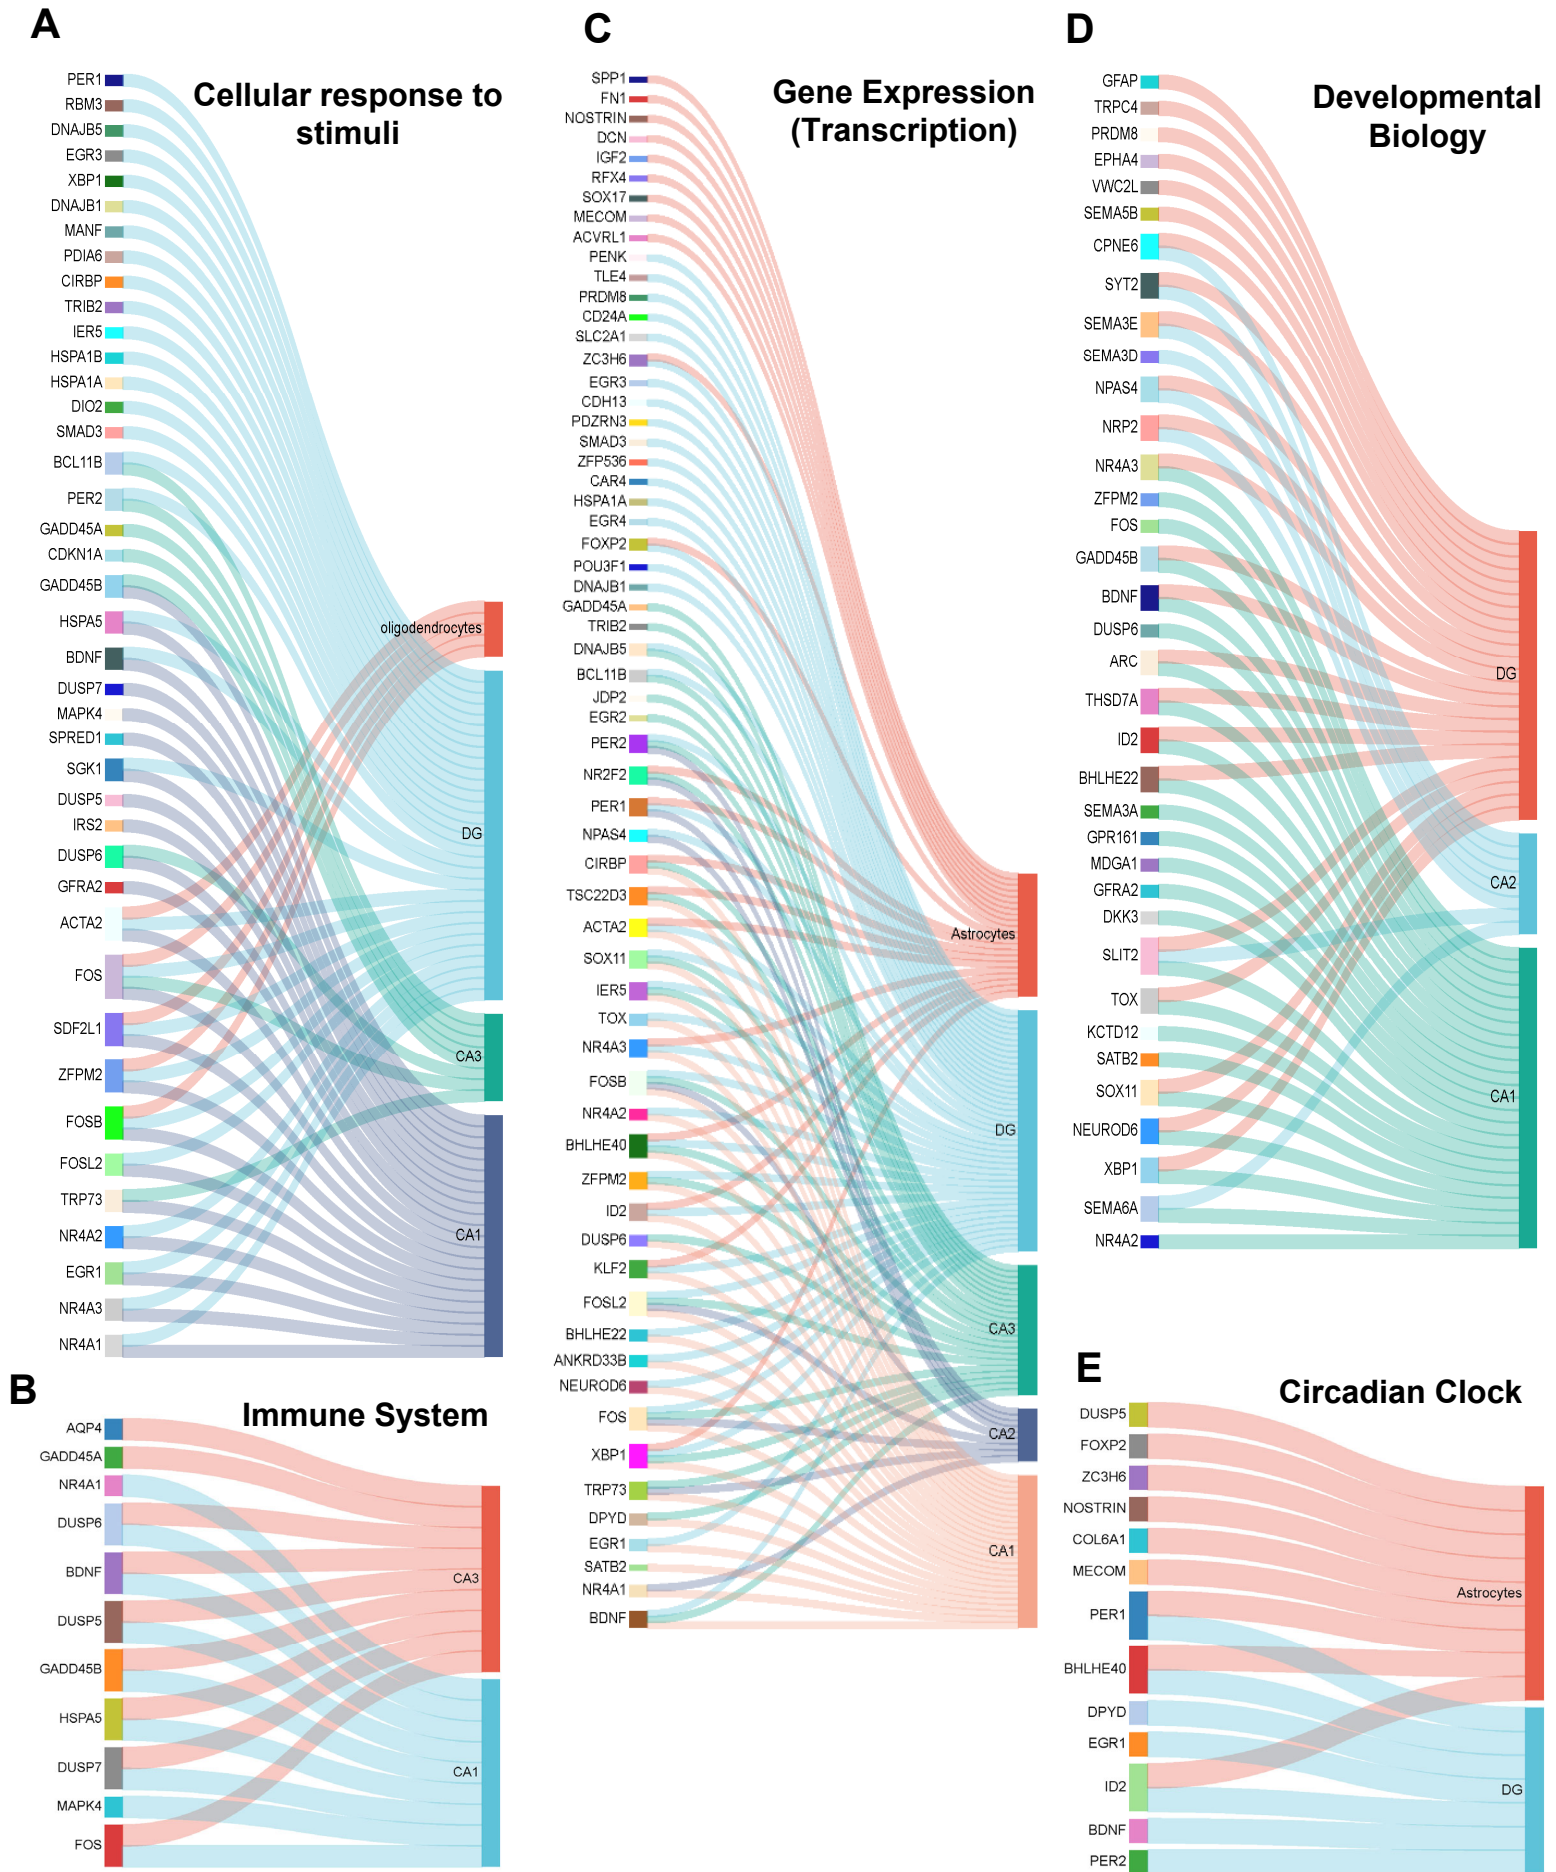

Figure 7:
Many genes annotated to the same clusters are not overlapped among the cell types (A-E).
